

# Neutrinoless double beta decay in the LHC era

Heinrich Päs

Erice 2009

Neutrinos in Cosmology, in Astro-, Particle- and Nuclear Physics

# Outline

- What is double beta decay
- A general parametrization
- New physics contributions - How to discriminate the mechanisms?
- Half life ratios
- Double beta decay and the LHC
- Summary and conclusions

# What is neutrinoless double beta decay?

$$2n \rightarrow 2p + 2e^-$$

## Mass mechanism:

$$[T_{1/2}^{0\nu}]^{-1} \propto \left| \sum_i U_{ei}^2 m_i \right|^2$$

In general: Every operator

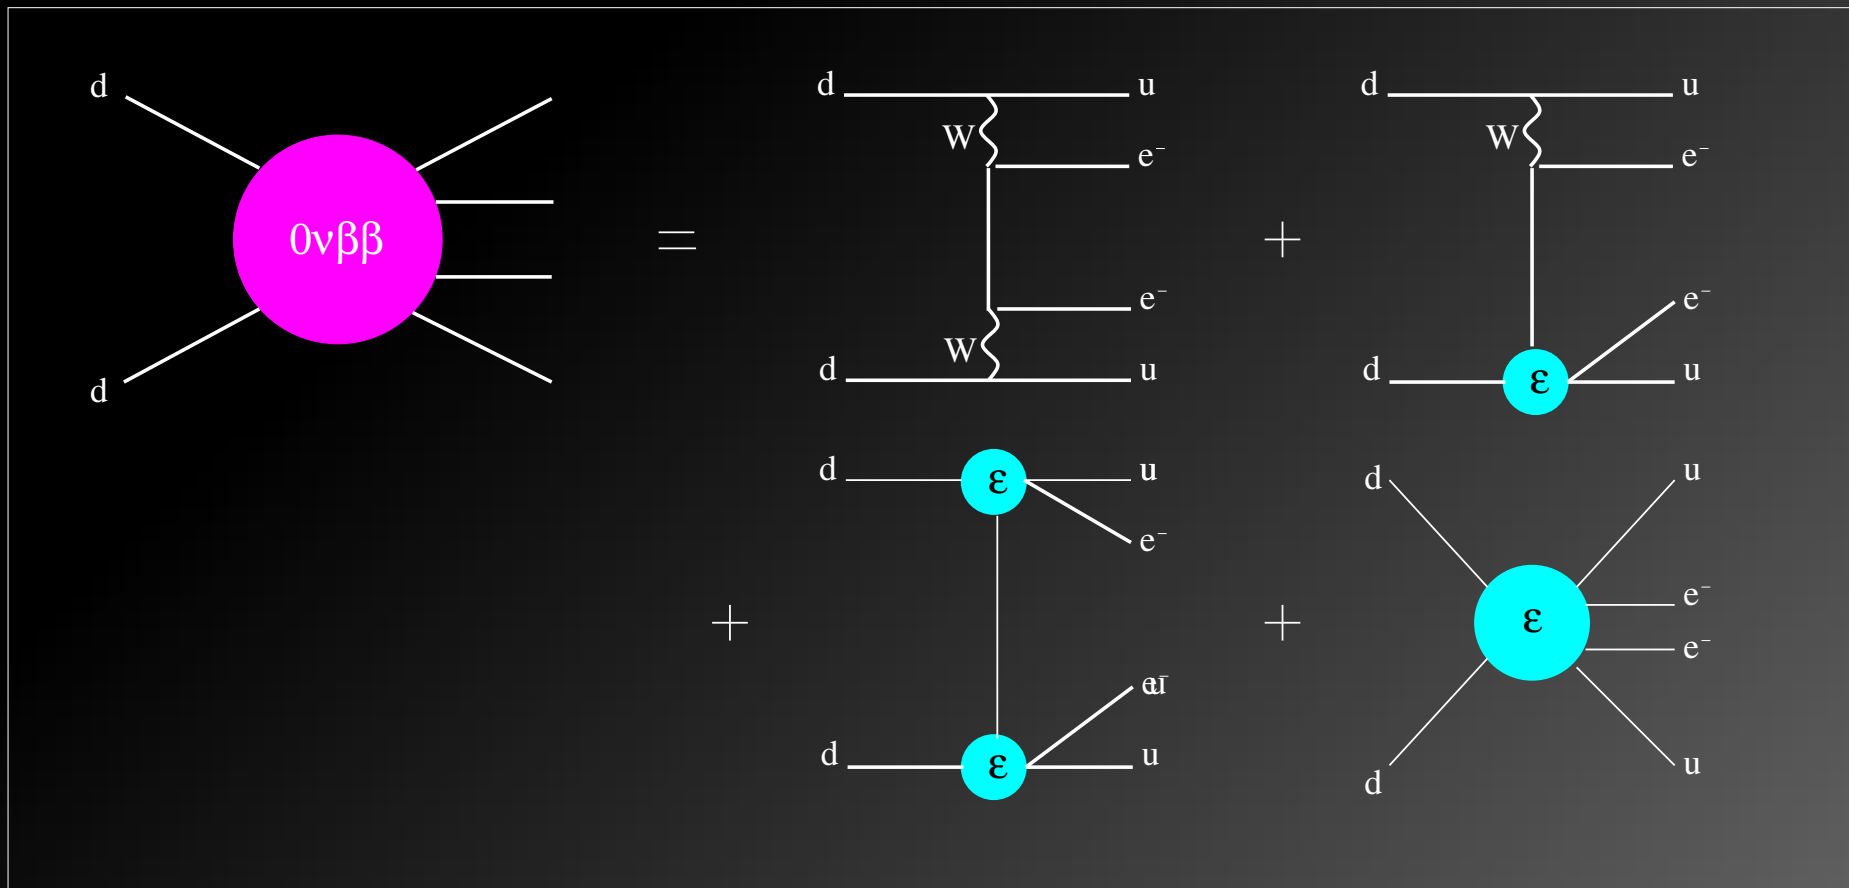

$$\bar{p} \bar{p} \bar{e} \bar{e} n n / M^5$$

will generate  $0\nu\beta\beta$  decay

# A general parametrization

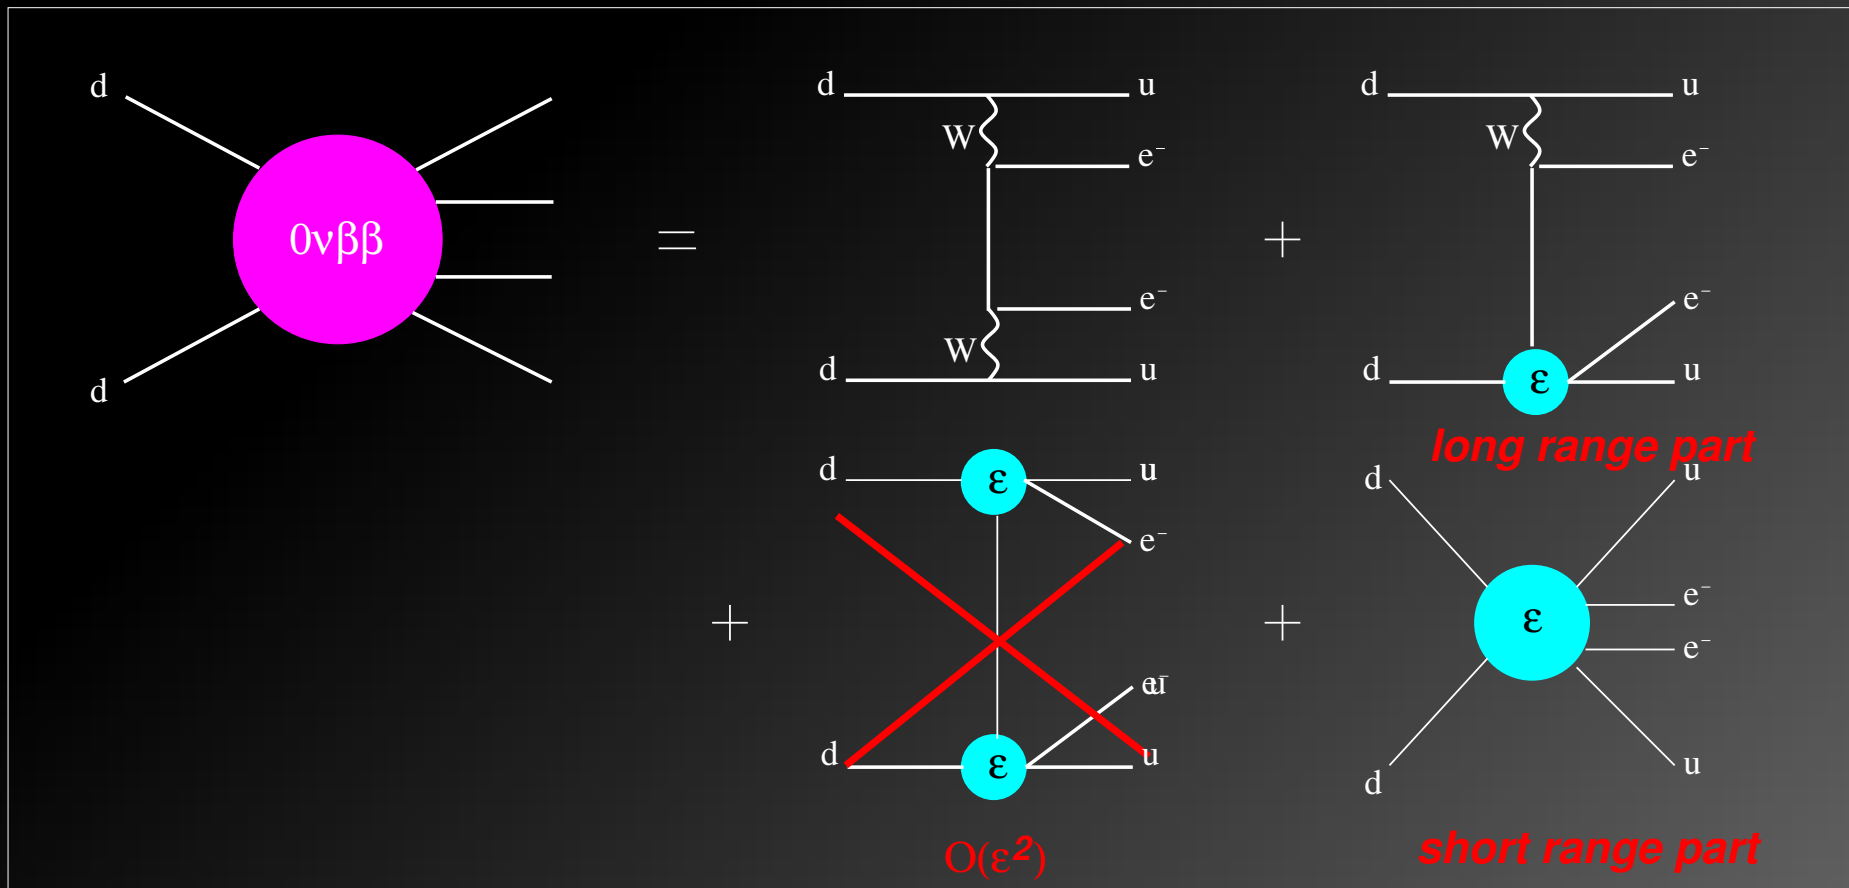

Expand in terms of vertices being point-like at the Fermi scale  
 $p_F \sim 100 \text{ MeV}$ :

Päs, Hirsch, Klapdor-Kleingrothaus, Kovalenko 1999 & 2001

# A general parametrization

Expand in terms of vertices being point-like at the Fermi scale  
 $p_F \sim 100 \text{ MeV}$ :

Päs, Hirsch, Klapdor-Kleingrothaus, Kovalenko 1999 & 2001

# A general parametrization

## Long range interaction

$$\mathcal{L} = \frac{G_F}{\sqrt{2}} \left( j_{V-A}^\mu J_{V-A,\mu} + \sum \epsilon_{NP} j_{NP} J_{NP} \right)$$

with hadronic and leptonic Lorentz currents of defined chirality:

$$J_{NP,V-A} = \bar{u} \mathcal{O}_J d \text{ and } j_{NP,V-A} = \bar{e} \mathcal{O}_j \nu$$

( $\mathcal{O}_{J,j}$ : transition operator     $\epsilon_{NP}$ : effective coupling strength)

## Short range interaction

$$\mathcal{L} = \frac{G_F^2}{2} m_p^{-1} \sum \epsilon_{NP} J_{NP} J_{NP} j'_{NP}$$

with hadronic and leptonic currents of defined chirality:

$$J_{NP} = \bar{u} \mathcal{O}_J d \text{ and } j'_{NP} = \bar{e} \mathcal{O}_j e^C$$

$$[T_{1/2}^{NP}]^{-1} = \epsilon_{NP}^2 G^{NP} |\mathcal{M}^{NP}|^2$$

→ calculate matrix elements for all Lorentz invariant combinations

Päs, Hirsch, Klapdor-Kleingrothaus, Kovalenko, 1999 & 2001

## A major problem

Uncontroversial detection of  $0\nu\beta\beta$  decay: uttermost importance!

- prove lepton number to be broken in Nature
- prove neutrinos to be Majorana particles *Schechter and Valle, 1982*

However: it will immediately generate another puzzle:

which mechanism that triggers the decay?

Without identification of the underlying mechanism:

- experimental evidence for  $0\nu\beta\beta$  decay will only provide **ambiguous information about the concrete physics underlying the decay!**
- **No information about  $m_\nu$  can be obtained from a measurement of the neutrinoless double beta decay half life!**

# SUSY-accompanied neutrinoless double beta decay

- integrating out a heavy  $d_k$ -squark
- $\mathcal{R}_P$  couplings  $\lambda'_{11k}$  and  $\lambda'_{1k1}$
- exchange of a light  $\nu_i$

$$\mathcal{L} \supset \frac{G_F U_{ei}^*}{4\sqrt{2}} \epsilon^{\text{SUSYacc}} \left[ (\bar{\nu}_i (1 + \gamma_5) e^c) (\bar{u} (1 + \gamma_5) d) + \frac{1}{2} (\bar{\nu}_i \sigma^{\mu\nu} (1 + \gamma_5) e^c) (\bar{u} \sigma^{\mu\nu} (1 + \gamma_5) d) \right]$$

New physics parameter:

$$\epsilon^{\text{SUSYacc}} = \sum_k \frac{\lambda'_{11k} \lambda'_{1k1}}{2\sqrt{2} G_F} \sin 2\theta_k \left( \frac{1}{m_{\tilde{d}_1}^2} - \frac{1}{m_{\tilde{d}_2}^2} \right) \theta_k: \text{LR-mixing of } \tilde{d}_1 \text{ and } \tilde{d}_2$$

Babu, Mohapatra, 1995; Hirsch, Klapdor-Kleingrothaus, Kovalenko, Päs, 1996 & 1999

# Glino exchange mechanism in R-parity violating SUSY

- integrating out  $u$ - and  $d$ -squarks and a gluino

$$\mathcal{L} \supset \frac{G_F^2}{2} m_p^{-1} \epsilon^{\tilde{g}} ((\bar{u}(1 + \gamma_5)d)(\bar{u}(1 + \gamma_5)d) - \frac{1}{4}(\bar{u}\sigma^{\mu\nu}(1 + \gamma_5)d)(\bar{u}\sigma^{\mu\nu}(1 + \gamma_5)d) (\bar{e}(1 + \gamma_5)e^c))$$

New physics parameter:

$$\epsilon^{\tilde{g}} = \frac{2\pi\alpha_s}{9} \frac{\lambda_{111}'^2}{G_F^2 m_{\tilde{d}_R}^4} \frac{m_p}{m_{\tilde{g}}} \left[ 1 + \left( \frac{m_{\tilde{d}_R}}{m_{\tilde{u}_L}} \right)^4 \right]$$

Mohapatra 1986; Vergados 1987; Hirsch, Klapdor-Kleingrothaus Kovalenko, 1996

# Right-handed currents

- Integrating out right-handed  $W$ -bosons occurring in left-right symmetric models

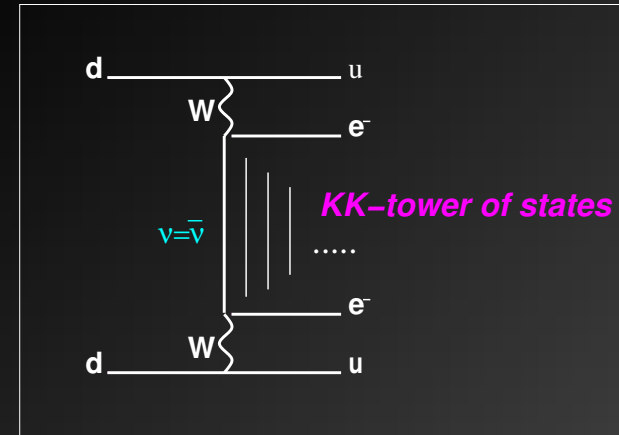

$$\mathcal{L} \supset \frac{G_F}{\sqrt{2}} (\bar{\nu}_i \gamma_\mu (1 + \gamma_5) e^c) \left( \eta (\bar{u} \gamma^\mu (1 - \gamma_5) d) + \lambda (\bar{u} \gamma^\mu (1 + \gamma_5) d) \right)$$

where the new physics parameters are given by  $\eta$  and  $\lambda$

Doi, Kotani, Nishiura, Takasugi, 1983

# Kaluza-Klein neutrino exchange in extra-dimensional models

- sum over all KK-excitations with masses  $m_{(n)}$
- weight with the mass dependent matrix element  $\mathcal{M}^{m_\nu}(m_{(n)})$

$$\epsilon^{KK} = \frac{1}{\mathcal{M}^{m_\nu}} \sum_{-\infty}^{\infty} U_{en}^2 m_{(n)} (\mathcal{M}^{m_\nu}(m_{(n)}) - \mathcal{M}^{m_\nu})$$

- $\epsilon^{KK}$  depends on NME  $\mathcal{M}^{m_\nu}(m_{(n)}) \Leftrightarrow$  particle physics does not decouple from the nuclear physics.
- KK excitations vary from values much smaller than the nuclear Fermi momentum  $p_F$  to values much larger than  $p_F$ , while the  $m_{(n)}$ -dependence of  $\mathcal{M}^{m_\nu}(m_{(n)})$  changes around  $p_F$
- KK spectrum fixed by choosing brane shift parameter  $a = 10 \text{ GeV}^{-1}$  and the radius of the extra dimension  $R = (1/300) \text{ eV}^{-1}$

Bhattacharyya, Klapdor-Kleingrothaus, Päs, Pilaftsis, 2003

# Half life ratios

- Concentrate on: different mechanisms result in different NMEs
- Problem: smaller NME for e.g. the mass mechanism as compared to any alternative new physics mechanism can be compensated by a larger value for the neutrino mass
- However: If one mechanism dominates  $\rightarrow \langle m_\nu \rangle$  or  $\epsilon_{NP}$  drops out in the ratio of experimentally determined half lives for two different emitter isotopes

$$\frac{T_{1/2}(^A X)}{T_{1/2}(^{76}\text{Ge})} = \frac{|\mathcal{M}(^{76}\text{Ge})|^2 G(^{76}\text{Ge})}{|\mathcal{M}(^A X)|^2 G(^A X)}$$

- $\Rightarrow$  Half life ratios depend on the mechanism of double beta decay, but not on the new physics parameter!
- Compare with theoretical prediction for different mechanisms!
- Error in NME ratio can be reduced compared to theoretical error in one matrix element (cancellations of systematic effects)!

# Results

F. Deppisch, H. Päs, *Phys. Rev. Lett.* **98** (2007) 232501

Matrix elements calculated in the QRPA approach of

A. Staudt, K. Muto and H. V. Klapdor-Kleingrothaus, *Europhys. Lett.* **13**, 31 (1990); M. Hirsch, K. Muto, T. Oda and H. V. Klapdor-Kleingrothaus, *Z. Phys. A* **347**, 151 (1994)

or taken from literature using the same code

See also: Gehmann, Elliott, 2007; Fogli, Lisi, Rotunno, 2009

# Results

- $R_P$  SUSY contributions:

similar and rather small deviations

Most effectively discriminated by comparing  $^{82}\text{Se}$  and  $^{136}\text{Xe}$  (60% variation)

- Left-right symmetric models:

strong deviations for  $\lambda\lambda$  combination, comparing  $^{128}\text{Te}$  and  $^{150}\text{Nd}$ :

$$\boxed{T_{1/2}^{LR} / T_{1/2}^{m_\nu} [^{128}\text{Te}] \gtrsim 20 \times T_{1/2}^{LR} / T_{1/2}^{m_\nu} [^{150}\text{Nd}]}$$

small deviations for  $\eta\eta$  combination comparison of  $^{100}\text{Mo}$  and  $^{136}\text{Xe}$  yields a variation of 70 %

- Extra-dimensional neutrino models with a large brane shift parameter:

large deviations for  $^{136}\text{Xe}$  and  $^{150}\text{Nd}$ :

$$\boxed{T_{1/2}^{KK} / T_{1/2}^{m_\nu} [^{150}\text{Nd}] \gtrsim 5 \times T_{1/2}^{KK} / T_{1/2}^{m_\nu} [^{100}\text{Mo}]}$$

Caution: strong deformation of  $^{150}\text{Nd}$  is ignored in most QRPA calculations

→ Simkovic, Pacearescu, Faessler, 2004

# Nuclear matrix element uncertainties

- **Theoretical errors** of NME calculation **dominate** experimental errors  $\Rightarrow$  difficult to determine the confidence level with which either mechanism can be excluded to generate the observed double beta evidence!
- Assuming e.g. a **statistical distribution** of matrix element values  $\Leftrightarrow$  **relative variation of 60%** in  $\mathcal{R}^{NP}(^A X)$  w.r.t.  $\mathcal{R}^{m\nu}(^A X)$  is **significant only if NMEs would be known with an accuracy of 15%**!  $\rightarrow$  **unrealistic!**
- **Estimates of uncertainties vary:** factor 3-5 (spread of published values) to **only 30%** (uncertainties inherent in QRPA) **Rodin, Faessler, Simkovic, Vogel, 2006**

## However:

- **significance will increase** if a **whole set of measurements** in different isotopes resembles the expected pattern
- **systematical effects** (like a too small  $g_{pp}$  in the pn-QRPA approach, a different  $g_A$ , higher-order terms, different model-space) **will cancel out**
- $\rightarrow$  **check results with alternative codes!**
- $\rightarrow$  **include pion exchange which may be dominating in some of the models discussed!** **Faessler, Kovalenko, Simkovic 1998; ...and Gutsche 2007**

# Alternative ideas

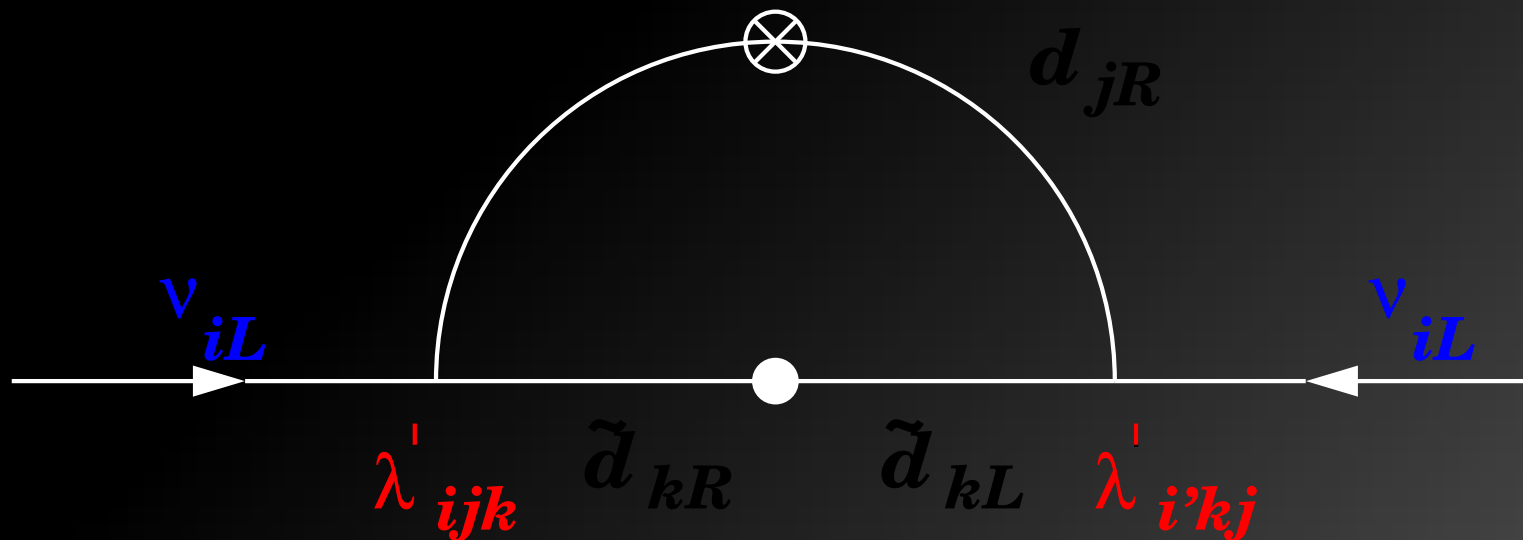

Possibilities to disentangle at least some of the possible mechanisms:

- analysis of **angular correlations** between the emitted electrons  
Doi, Kotani, Nishiura and Takasugi, 1983; Ali, Borisov and Zhuridov, 2006 & 2007  
→ **few experiments** sensitive to electron tracks
- comparative study of  $0\nu\beta\beta$  and  $0\nu\beta^+$  with **electron capture (*EC*) decay**  
Hirsch, Muto, Oda, Klapdor-Kleingrothaus, 1994  
→ **small rates** and **experimental challenge** to observe the produced X-rays or Auger electrons
- study of **double beta decay to excited  $0^+$  states**  
Simkovic, Nowak, Kaminski, Raduta, Faessler, 2001  
→ **few experiments** sensitive to transitions to excited states.

# RPV vs. $m_{ee}$ in mSUGRA

Couplings which generate direct RPV contributions also generate  $m_{ee}$ :

- $\lambda'_{112}\lambda'_{121}$ : **excluded** by bounds from  $K_0 - \bar{K}_0$  mixing
- $\lambda'_{113}\lambda'_{131}$ : **direct RPV and  $m_{ee}$  comparable**
- $\lambda'_{111}{}^2$ : **direct RPV dominates**

B.C. Allanach, C.H. Kom, H. Päs, Phys. Rev. Lett. 103 (2009) 091801

# Complementary observables: LHC and B physics

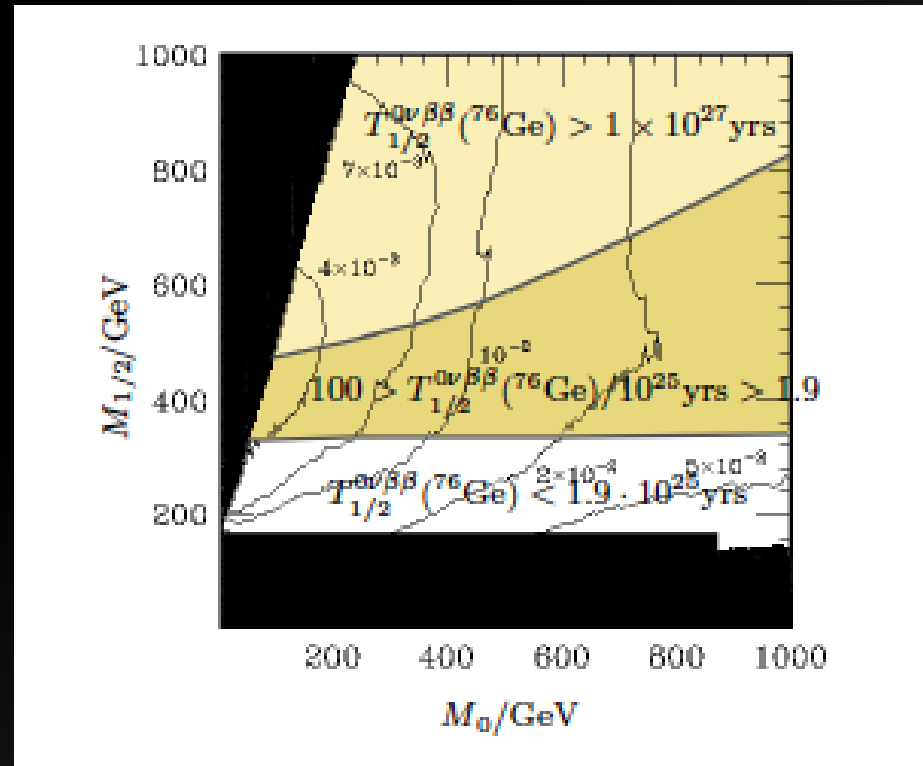

- $\lambda'_{113}\lambda'_{131}$ : if  $B$  meson mass difference entirely due to trilinear RPV  $\Rightarrow 0\nu\beta\beta$  observable in next generation (100 kg) experiments (depending on NME!)
- $\lambda'_{111}{}^2$ : LSD signal from single selectron production observable at the LHC  $\rightarrow$  possibility of determination of  $\lambda'_{111}$

B.C. Allanach, C.H. Kom, H. Päs, arXiv:0903.0347

# Outlook: Neutrino masses at the LHC

# Outlook: Neutrino masses at the LHC

- Seesaw I + SUSY  $\rightarrow$  LFV decays ( $\tau \rightarrow \mu\gamma$ ), slepton mass splittings  
Deppisch, Päs, Redelbach, Rückl, Shimizu, 2003; Deppisch, Freitas, Porod, Zerwas, 2008
- Trinification ( $SU(3)_C \times SU(3)_L \times SU(3)_R$ ) + SUSY  $\Rightarrow$  Inverse Seesaw  $\Rightarrow$  New physics at TeV scale! Cauet, Päs, Wiesenfeldt, work in progress
- $S_3$  flavor symmetry  $\Rightarrow$  3 Higgs doublets  $\Rightarrow$  flavor violating and flavor specific Higgs decays at the LHC! Bhattacharyya, Leser, Päs, work in progress

## Helmholtz Alliance Terascale Working group: Neutrino masses and Lepton Flavor violation at the LHC

Theory groups from Dortmund (Päs) and Würzburg (Porod) and Experimentalists from Dortmund, Würzburg (Gößling, Trefzger, ATLAS), Aachen (CMS)

# Summary and conclusions

- There exist several alternatives to the mass mechanism for  $0\nu\beta\beta$  decay
- different mechanisms of neutrinoless double beta decay would manifest themselves in half life ratios involving different isotopes
- Strong discriminators for at least some mechanisms (LR symmetry, KK excitations)
- Motivation for measurements in different isotopes!
- Motivation to search for alternative observables
- $B\bar{B}$  mixing bound:  $0\nu\beta\beta$  due to  $\lambda'_{113}\lambda'_{131}$  RPV only in next generation experiments
- Single selectron production at the LHC: observation possible in large areas of the parameter space if  $0\nu\beta\beta$  is due to  $\lambda'_{111}{}^2$  RPV!
- Exploration of the TeV scale at LHC will be crucial for a variety of approaches to explain the generation of neutrino masses
