- **5** EVALUATION OF  $e^+e^- o M\bar{M}$  AND  $e^+e^- o \gamma M$  CONTRIBUTIONS TO MUON g-2 AND  $\alpha(M_Z^2)$
- **6** CONCLUSIONS

#### The anomalous magnetic moment of the muon

$$a_{\mu}=rac{g-2}{2}$$
,

to be measured experimentally and evaluated theoretically, provides an **extremely clean test of the Standard Model (SM)** of elementary particle physics.

Therefore - it is important to achieve in its evaluation the inequality

$$(a_{\mu}^{\mathsf{exp}} - a_{\mu}^{\mathsf{th}}) < \Delta(a_{\mu}^{\mathsf{exp}} - a_{\mu}^{\mathsf{th}}).$$

Another quantity - the running QED fine structure coupling constant

$$\alpha(M_Z^2)$$
,

is also very important to be known with very high precision - as almost all SM predictions of observable depend on its value.

In both quantities,

$$a_{\mu}$$
 and  $\alpha(M_Z^2)$ ,

dominant sources of the total uncertainties in theoretical predictions are hadronic contributions, which can be reduced to the calculation of dispersion integrals through

$$\sigma_{tot}(e^+e^- \rightarrow hadrons)$$
.

Almost all evaluations of these integrals have been carried out by the integration through existing experimental data points on  $\sigma_{tot}(e^+e^- \to hadrons)$ , joining them by straight lines, i.e. by using the so-called "trapezoidal rule".

In this contribution we would like to demonstrate, how the errors of the evaluated integrals through two-body total cross-sections  $\sigma(e^+e^-\to M\bar{M})$  and  $\sigma(e^+e^-\to \gamma M)$  can be reduced by exploiting the Unitary and Analytic (U& A) model of EM structure of the nonet of pseudoscalar mesons

$$\pi^+, \pi^0, \pi^-, K^+, K^0, \bar{K}^0, K^-, \eta, \eta'$$

in comparison with evaluation of the same integrals and at the same energy intervals by the numerical integration through experimental points.

All charged leptons,  $e^-, \mu^-, \tau^-$  (and also their antiparticles) are described by the Dirac equation.

The magnetic moments of these particles are related to the spin by means of the expression

$$\vec{\mu} = g\left(\frac{e}{2m_l}\right)\vec{s} \tag{1}$$

where the value of **gyromagnetic ratio** *g* is predicted theoretically *I.J.R.Aitchison and A.J.G.Hey: Gauge theories in particle physics, Bristol and Philadelphia, 2003* 

to be g=2.

However, interactions existing in nature  $modify\ g$  to be exceeding the value "2" because of the emission and absorption of

- virtual photons (EM effects)
- intermediate vector and Higgs bosons (weak interaction effects)
- vacuum polarization into virtual hadronic states (strong interaction effects)

#### Note:

This is true for all three charged leptons,  $e^-, \mu^-, \tau^-$ .

In order to describe this modification of g theoretically, the **magnetic anomaly** has been introduced by the relation

$$a_{l} = \frac{g-2}{2} = a_{l}^{(1)} \left(\frac{\alpha}{\pi}\right) + \left(a_{l}^{(2)QED} + a_{l}^{(2)had}\right) \left(\frac{\alpha}{\pi}\right)^{2} + a_{l}^{(2)weak} + O\left(\frac{\alpha}{\pi}\right)^{3}$$

$$(2)$$

where  $\alpha$  is the fine structure constant of QED to be  $\alpha(0) = \frac{1}{137,036}$ .

While **contribution of**  $a_I^{(2)weak}$  to the lepton g-2 anomaly  $a_I$  in comparison with  $a_I^{(2)QED}$  and  $a_I^{(2)had}$  is **tiny** for all charged leptons, the **hadronic contribution**  $a_I^{(2)had}$  i.e.  $\frac{a_I^{(2)had}}{a_I^{(2)QED}}$  is **increasing with an increase of the lepton mass**.

So, if one would like to look for new physics beyond the SM (investigating hadronic contributions) the most suitable object could be the anomalous magnetic moment of the  $\tau^-$ -lepton  $a_{\tau}$ .

But its experimental measurement is difficult to be carried out due to the instability of the  $\tau^-$  particle.

On the other hand, the **electron anomalous magnetic moment**  $a_e^{\text{exp}} = 1159652180, 73(0, 28) \times 10^{-12}$ 

is theoretically almost completely described by QED

Aoyama, Hayakawa, Kinoshita, Nio (2014)

i.e. it is not sensitive to hadronic contributions.

Its theoretical error is dominated only by the uncertainty in the input value of the QED fine structure coupling constant  $\alpha$ .

The muon anomalous magnetic moment  $a_{\mu}$  - the most suitable object for theoretical investigations:

- one of the best measured quantities in physics  $a_{\mu}^{(BNL)}=116592080(63)\times 10^{-11}$
- though its present accurate theoretical evaluation  $a_{\mu}^{SM}=116591802(49)\times 10^{-11}$  is still lower than  $a_{\mu}^{exp}$   $a_{\mu}^{(BNL)}-a_{\mu}^{SM}=278(80);\ 3.6\sigma,$  but further theoretical and experimental improvements may lead to a revelation of a new physics beyond SM.
- moreover, a **new measurement of it is expected in 2017**G. Venanzoni: The FERMILAB muon g-2 experiment E989,
  Contr. to FPS HFP'15 in Vienna

The hadronic contributions  $a_{\mu}^{had}$  - represented by

Fig.1: The lowest-order hadronic vacuum-polarization contributions.

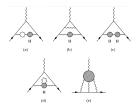

Fig.2: The third-order hadronic vacuum-polarization contributions.

Some time ago we have evaluated a contribution of the light-by-light (LBL) diagram (the last one in Fig. 2)

E.Bartos, A.Z.Dubnickova, S.Dubnicka, E.A.Kuraev, E.Zemlyanaya: Nucl. Phys. B632 (2002) 330 to be

$$a_{\mu}^{LBL} = (111.20 \pm 16.81) \times 10^{-11}$$

however the most accurate value has been obtained recently by

A.Dorokhov et al: Contr. to the HS'15 Conf. in Horny Smokovec, Slovakia

$$a_{\mu}^{LBL} = (168.0 \pm 12.5) imes 10^{-11}$$

We do not see any possibility of an improvement in evaluation of all the rest of the third-order hadronic vacuum-polarization diagrams in Fig. 2, in comparison with the recent precise evaluation carried out by

A.Kurz et al: Phys. Lett B (2014)

However, we see **substantial improvement in evaluation** of the **lowest-order hadronic vacuum-polarization diagram in Fig.1**, which can be represented

M.Gourdin, E. de Rafael: Nucl. Phys. B10 (1969) 667

by the dispersion integral

$$a_{\mu}^{(2)had} = \frac{1}{3} \left(\frac{\alpha(0)}{\pi}\right)^2 \left(\int_{4m_{\pi}^2}^{s_{(cut)}} \frac{ds}{s} R^{data}(s) K(s) + \int_{s_{(cut)}}^{\infty} \frac{ds}{s} R^{pQCD}(s) K(s)\right)$$
(3)

with

$$R(s) = \sigma_{tot}(e^+e^- o had)/rac{4\pi\alpha(0)^2}{3s}$$

and

$$K(s) = \int_0^1 dx \frac{x^2(1-x)}{x^2+(1-x)\frac{s}{m_{tL}^2}}$$

Just in the first integral of (3) instead of integration through data on  $\sigma_{tot}(e^+e^- \to had)$  we evaluate contributions separately of

$$\sigma_{tot}(e^{+}e^{-} \to \pi^{+}\pi^{-}) = \frac{\pi\alpha(0)^{2}}{3s} (1 - 4m_{\pi}^{2}/s)^{\frac{3}{2}} |F_{\pi^{\pm}}(s)|^{2}$$

$$\sigma_{tot}(e^{+}e^{-} \to K^{+}K^{-}) = \frac{\pi\alpha(0)^{2}}{3s} (1 - 4m_{K^{\pm}}^{2}/s)^{\frac{3}{2}} |F_{K^{\pm}}(s)|^{2}$$

$$\sigma_{tot}(e^{+}e^{-} \to K^{0}\bar{K}^{0}) = \frac{\pi\alpha(0)^{2}}{3s} (1 - 4m_{K^{0}}^{2}/s)^{\frac{3}{2}} |F_{K^{0}}(s)|^{2}$$

$$\sigma_{tot}(e^{+}e^{-} \to \pi^{0}\gamma) = \frac{\pi\alpha(0)^{2}}{6} (1 - m_{\pi^{0}}^{2}/s)^{3} |F_{\pi^{0}\gamma}(s)|^{2}$$

$$\sigma_{tot}(e^{+}e^{-} \to \eta\gamma) = \frac{\pi\alpha(0)^{2}}{6} (1 - m_{\eta^{\prime}}^{2}/s)^{3} |F_{\eta\gamma}(s)|^{2}$$

$$\sigma_{tot}(e^{+}e^{-} \to \eta^{\prime}\gamma) = \frac{\pi\alpha(0)^{2}}{6} (1 - m_{\eta^{\prime}}^{2}/s)^{3} |F_{\eta^{\prime}\gamma}(s)|^{2}$$

## FINE STRUCTURE CONSTANT OF QED $\alpha(s)$ at $M_Z^2$

The running fine structure coupling constant of QED  $\alpha(s)$  can be expressed as

$$\alpha(s) = \frac{\alpha(0)}{1 - \Delta\alpha(s)}; \quad \alpha(0) = 1/137,036$$
 (4)

whereby  $\Delta \alpha(s)$  is governed by the **renormalized vacuum** polarization function  $\Pi_{\gamma}(s)$ .

# FINE STRUCTURE CONSTANT OF QED $\alpha(s)$ at $M_Z^2$

 $\Pi_{\gamma}(s)$  is defined by the Fourier transform of the time-ordered product of the **EM currents**  $J_{em}^{\mu}(s)$  in the vacuum

$$(q^{\mu}q^{\nu} - q^{2}g^{\mu\nu})\Pi_{\gamma}(q^{2}) = i \int d^{4}x e^{iqx} < 0 \mid T[j_{em}^{\mu}(x)j_{em}^{\nu}(0)] \mid 0 >$$
(5)

as

$$\Delta \alpha(s) = -4\pi\alpha(0)Re[\Pi_{\gamma}(s) - \Pi_{\gamma}(0)]. \tag{6}$$

**NOTE**: The  $\Delta\alpha(s)$ , for instance at  $s=M_Z^2$  is large - due to the large change in scale, going from  $s\to 0$  (Thomson limit) to the mass of Z resonance.

# FINE STRUCTURE CONSTANT OF QED lpha(s) at $M_Z^2$

In perturbation theory, the **leading order contributions** represented by the free fermion loops (see Fig. 3)

$$\Delta \alpha = \sum_{f} \sqrt{f} \sqrt{f}$$

Fig.3: The leading light fermion ( $m_f \ll M_Z$ ) contributions.

give

$$\Delta\alpha(s) = \frac{\alpha(0)}{3\pi} \sum_{f} Q^2 N_{cf} \left( \ln \frac{s}{m_f^2} - \frac{5}{3} \right) \tag{7}$$

where Q... the fermion charge;  $N_{cf}$ ...the color factor - 1 for **leptons** and 3 for **quarks**.

## FINE STRUCTURE CONSTANT OF QED $\alpha(s)$ at $M_Z^2$

One distinguishes contributions in  $\Delta \alpha(s)$ 

- from leptons  $(e, \mu, \tau)$
- from 5 light quarks u, d, c, s, b (mass < 5 GeV)
- from "top" quark  $t \; (mass \approx 175 \, GeV)$

Then

$$\Delta \alpha(s) = \Delta \alpha_I(s) + \Delta_{had}^{(5)}(s) + \Delta \alpha_{top}(s). \tag{8}$$

# FINE STRUCTURE CONSTANT OF QED $\alpha(s)$ at $M_Z^2$

The **leptonic contributions** are calculable in perturbation theory, where at leading order the free leptons yield

$$\Delta \alpha_I(s) = \frac{\alpha(0)}{3\pi} \sum_{f=e,\mu,\tau} \left[ \ln \frac{s}{m_I^2} - \frac{5}{3} \right]$$
 (9)

Then numerically  $\Delta \alpha_I(M_Z^2) \approx 0.031498$ .

# FINE STRUCTURE CONSTANT OF QED lpha(s) at $M_Z^2$

Since the *t*-quark is heavy  $(m_t \gg M_Z \approx 91 \, \text{GeV})$ , one can not use the light fermion approximation for it and it decouples like

$$\Delta \alpha_{top}(s) \approx -\frac{\alpha(0)}{3\pi} \frac{4}{15} \frac{M_Z^2}{m_t} \to 0.$$
 (10)

# FINE STRUCTURE CONSTANT OF QED $\alpha(s)$ at $M_Z^2$

A serious problem is the 5 light quarks, u, d, s, c, b contribution  $\Delta\alpha_{had}^{(5)}(s)$ , due to the light masses of these quarks it can not be calculated in the framework of the "perturbative" QCD (pQCD).

Fortunately - one can evaluate it from  $e^+e^- \to hadrons$  data, like in muon g-2 anomaly, by exploiting dispersion relation

$$Re\Pi_{\gamma}(s) - \Pi_{\gamma}(0) = \frac{s}{\pi} Re \int_{s_0}^{\infty} \frac{Im\Pi_{\gamma}(s')}{s'(s'-s-i\varepsilon)} ds'$$
 (11)

and the optical theorem

$$Im\Pi_{\gamma}(s) = \frac{s}{e^2} \sigma_{tot}(e^+e^- \to had).$$
 (12)

# FINE STRUCTURE CONSTANT OF QED $\alpha(s)$ at $M_Z^2$

In terms of the total cross-section ratio

$$R(s) = \frac{\sigma_{tot}(e^+e^- \to had)}{\sigma_{tot}(e^+e^- \to \mu^+\mu^-)},$$
 (13)

where

$$\sigma_{tot}(e^+e^- \to \mu^+\mu^-) = \frac{4\pi\alpha^2(0)}{3s}$$
 (14)

one finally obtains

$$\Delta \alpha_{had}^{(5)}(M_Z^2) = -\frac{\alpha(0)M_Z^2}{3\pi} Re \int_{4m_\pi^2}^{\infty} \frac{R(s')}{s'(s' - M_Z^2 - i\varepsilon)} ds'.$$
 (15)

In construction of the U&A model, EM FFs in  $\sigma(e^+e^- \to M\bar{M})$  and  $\sigma(e^+e^- \to \gamma M)$  are splitted into isoscalar and isovector parts

$$F_{\pi^{\pm}}(s) = F_{\pi}^{I=1}[W(s)]$$

$$F_{K^{\pm}}(s) = F_{K}^{I=0}[V(s)] + F_{K}^{I=1}[W(s)]$$

$$F_{K^0}(s) = F_K^{I=0}[V(s)] - F_K^{I=1}[W(s)]$$

$$F_{\pi^0\gamma}(s) = F_{\pi^0\gamma}^{I=0}[V(s)] + F_{\pi^0\gamma}^{I=1}[W(s)]$$

$$F_{\eta\gamma}(s) = F_{\eta\gamma}^{I=0}[V(s)] + F_{\eta\gamma}^{I=1}[W(s)]$$

$$F_{\eta'\gamma}(s) = F_{\eta'\gamma}^{I=0}[V(s)] + F_{\eta'\gamma}^{I=1}[W(s)].$$

The model takes into account all known properties of FFs:

- normalization of FFs
- asymtotic behaviour as predicted by the quark model
- analytic properties of FFs
- unitarity conditions of FFs
- reality conditions of FFs
- experimental fact of a creation of vector mesons in  $e^+e^- o had$  process
- then  $F^{l=1}(s)$  are **saturated** by  $\rho, \rho', \rho'',$  etc and  $F^{l=0}(s)$  by  $\omega, \phi, \omega', \phi',$  etc.

Finally, every  $F^{I=1}[W(s)]$  and  $F^{I=0}[V(s)]$  represent one analytic function in the whole complex s-plane besides two cuts on the positive real axis to be defined on the four-sheeted Riemann surface and depend on only physically interpretable parameters.

To every considered vector meson, complex conjugate pair of poles on unphysical sheets appear.

Their **predictions** for the **nonet of pseudoscalar mesons** are presented in the following Figs.

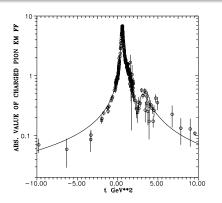

Figure: Prediction of pion EM FF behavior by U&A model.

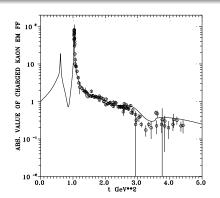

Figure: Prediction of charge kaon EM FF behavior by U&A model.

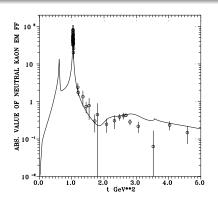

Figure: Prediction of neutral kaon EM FF behavior by U&A model.

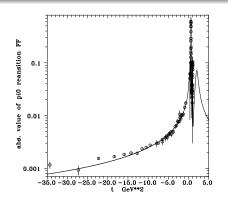

Figure: Prediction of  $\pi^0 \gamma$  transition EM FF behavior by U&A model.

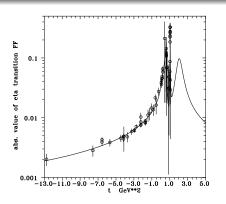

Figure: Prediction of  $\eta \gamma$  transition EM FF behavior by U&A model.

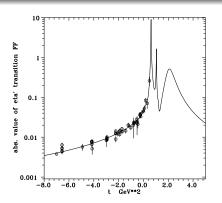

Figure: Prediction of  $\eta'\gamma$  transition EM FF behavior by U&A model.

Substituting U&A models of  $F^{l=1}[W(s)]$  and  $F^{l=0}[V(s)]$  with corresponding numerical values of parameters into two-body total cross-sections  $\sigma(e^+e^-\to M\bar{M})$  and  $\sigma(e^+e^-\to \gamma M)$ , one is ready to evaluate LO contributions to muon g-2 and  $\alpha(M_Z^2)$ . In order to have an opportunity to compare our results with other authors, we shall carry out both, direct data integration and also integration by exploiting the U&A model of the corresponding FFs, at the interval of energies  $s_0 < s < 2.0449 \, GeV^2$ .

#### Results for the muon g-2 anomaly:

$$a_{\mu}^{had,LO}(e^+e^-\to\pi^+\pi^-)\times 10^{-11} \text{ for } 4m_{\pi}^2 < s < 2.0449 GeV^2$$
   
  $U\&A$  model integration....5128,  $22_{-0,67}^{+0,73}$  direct data integration....5031,  $22_{-16,43}^{+28,94}$  K.Hagiwara et al (2007)....5008,  $2\pm28,70$ 

$$a_{\mu}^{had,LO}(e^+e^-\to K^+K^-)\times 10^{-11} \text{ for } 4m_K^2 < s < 2.0449 \, GeV^2$$
   
  $U\&A$  model integration....224,  $67^{+1,23}_{-1,28}$  direct data integration.....235,  $76^{+9,07}_{-5,00}$  K.Hagiwara et al  $(2004)$ .....216,  $2\pm7$ ,  $6$

 M.Davier et al (2011)...... ?

The best present evaluation of the hadronic contribution to the RUNNING FINE STRUCTURE CONSTANT OF QED  $\alpha(s)$  is

$$\Delta \alpha_{had}^{(5)}(M_Z^2) = 0.027896 \pm 0.000395$$

If we add this result to the calculated value of

$$\Delta_{leptons}(M_Z^2) = 0.031498,$$

then for  $\alpha(s)$  at the mass of the Z-boson one obtains

$$\alpha(m_Z^2) = \frac{\alpha(0)}{1 - 0.059394} = 1/128,897.$$

However, by exploiting our *U&A* model of the EM structure of pseudoscalar mesons **one can still improve this result substantially**.

#### Conclusions

What are the most important sources contributing to error reduction in the muon g-2 anomaly and in the running fine structure constant of QED?

#### Conclusions

- The U&A model takes into account all known theoretical properties of the considered EM FFs and always describes the experimental data by a single analytic function in the space-like and time-like region simultaneously.
- The U&A model depends on only physically interpretable parameters to be determined in a fitting of the data also outside the integration region, which leads to a decrease of the errors
- The U&A model predictions are mainly given by data with small errors and to large extent neglect the data points with huge uncertainties. Just the latter contribute importantly to the result error in the direct integration through data points!

# Thank you for your attention.
